## **Linear Regression Versus Random Forest Regression**

# Thomas Fishwick

Problem Description
In this datase we have 17,965 rows of data about used Ford cars and nine columns with their model, registration year, price, transmission type, mileage, fuel type, road tax, miles per gallon and engine size. From this data we are going to predict the price of a car from some, or all, of the remaining eight columns. We are going to be bodding back 30% of the dataset for testing and training on the remaining of the remaining of the columns. We are going to be bodding back 30% of the dataset for testing and training on the remaining of the remaining of the columns. We are going to be bodding back 30% of the dataset for testing and training on the remaining of t

many statistics.

Post Change

From this we can see that the maximum registration year is 2000, which is wrong, as a car can't be registered in the future (it is one car, which we will update to 2020), as that is assumed to be what it should be). For the engine size we have \$1 petrol, diesed and hybrid cars with an engine size of 0 (the two electric can's have an engine size of 2 (litros, which is self-ar failled runther or incorrect, as the "engine size is the amount of air and fail that can be forced into the cylinders of the engine" [1]).

For row, where the engine size is zer, we may engine size is zer, we manifest that engine size is ser, we may engine size is zer, we have \$1 petrol, diesed and hybrid cars will have a non-zero-engine size. For the engine size of \$1 petrol.

The engine size is zer, we have \$1 petrol, diesed and hybrid cars will have a non-zero engine size. For the engine size of \$1 petrol.

The engine size is zer, we have \$1 petrol, diesed and hybrid cars will have a non-zero engine size. For the engine size of \$1 petrol.

The engine size is zer, we have \$1 petrol.

The engine size is zer, we have \$1 petrol.

The engine size is zer, we have \$1 petrol.

The engine size is zer, we have \$1 petrol.

The engine size is zer, we have \$1 petrol.

as eague size of 0 (the two electric can have as engine size is of 2 libre, which is either a filler number or incorrect, as the "major size is the amount of air and fiel that can be feed and the equine size is not not recovery the power of the ferrow, where the engine size is not not convey the power of the ferrow, where the engine size is not not convey the power of the ferrow, where the engine size is not not convey the power of the ferrow, where the engine size is not not convey the power of the ferrow, where the engine size is not not convey the power of the ferrow, where the engine size is not not convey the power of the ferrow, where the engine size is not not convey the power of the ferrow, where the engine size is not not convey the power of the ferrow, where the engine size is not not convey the power of the ferrow, where the engine size is not not convey the power of the ferrow, where the engine size is not not convey the power of the ferrow of the engine size is not not convey the power of the ferrow of the engine size is not not convey the power of the ferrow of the engine size is not not convey the power of the ferrow of the engine size is not not seen to the engine size is not not convey the power of the ferrow of the engine size is not not seen that the engine size is not not seen to the engine size is not not seen that the engine size is not seen that the engine size is not not seen that the engine size is not seen that the is not engine size in the engine size is not seen that the is not engine si

Finally, the engine size column against price looks like it has something of a linear relation iship (with a lot of missing points).

The solution to linear regression is easy to use and can be easily transferred over to other systems
Using the solution to linear regression is just putting the relevant values for the X vector in and then using the w vector and intercept to find the y value (though you may have to rescale the X vector first)

A "way of centually his model to in cultical earlier artifactor, explained an interaction trent, which is constructed by computing the product of XI and XI<sup>2</sup> [6]. This allows the Linear Regression model to capture more complicated relationships such as year times

ex:

The solution might not make that much sense to people, as it may attach undue importance to particular variables if every possible variable has been put into the model (e.g. we may have the weather of when the car went to the dealership, which might be found to be useful by the computer/
Generally the model needs normalised data
Important assumption in linear modelings in the assumption of linearity" [3]

"The bias of the full model is equivalent to the bias of a single decision tree. The variance of the final model can be greatly reduced over that of a single tree" [7]

As it is a combination of many decision tree regressor models, the reason why it came up with a particular result can be hard to understand. It is not the black box of a neural network model, as we have access to the underlying trees, but effectively the why is buried in the detail of the trees You need to use the full model in production, you can't just pluck the W vector

Our logs below is in that the Random Front Regressor will have better accuracy, (lower MAE and RNSE) than Linear Regression in predicting price. This is because the random forest regressors should be able to generalise better to all of the different columns and pick up on smaller patterns. By contrast, linear regressions in just two places all injust two places all injustic places all injust two places all injust two places all injustic places all injust two places all injust two places all injustic places all injust two places all injust two places all injustic places all injust two pla

Choice of Training and Evaluation Methodology

We are using Mean Absolute Erne for decksing the sureage ernor and the Root Mean Squared Erner to see if there are higher errors (as RMSE penalises high errors more). We are also charring the predictions and real results against each other to see graphically what the errors are like and charting a histogram of the results have been seen that by are normally distributed and within a reasonable range. We have also calculated the Normalised Mean Squared Erner so that we can see a percentage error.

Analysis and critical evaluation of results
From the RMSE and MAE and RMSE and RMSE

price (admitted) these are on the normalised data, but you could translate them back to the unnormalized data). From the feature importance graphs (whose scales caused directly) computed, were the life and the forest deem's really use model. Excort, model ranger, model streetla, model translat. Lessons Learned and Future work.

Something we spotted as a potential issue and possible improvement when trying to analyse the models, was that there were a lot of binary columns as a what model care was. For random forest this is unlikely to be an issue, but could be something that didn't help the Linear Regression model. It might have been better to group the models into categories such as SUV, sports or, people carrier, etc. This at least would mean that you could train a model or new's are afth and then take the data for moder numufacture and see how well it precise their price (the model may not be a ware of the subtlety

that a Mercedes car with all the same variables as a Ford car might be perceived as more valuable due to its brand).

Choice of parameters and apportions that roads.

We have closes to use the columns model, year, misage, fiel type, MPG and engine size. This is because all of these have some relationship with the price column and aren't derived from other columns. Using the script Optimized interacting responsion we found the general parameters for linear regression that gave good results. Normalising the data dimunifically improved the performance of linear regression.

The best Linear Regression model than RMSE 1818/02 and MARF of 1344.83.

Lambein. 2000/01001;) the regularisation parameter used to penalise large coefficients.

For the Random Forest regressor we used the script OptimiseRandomForest to find the best hyperparameters.

The best Random Forest model has RMSE 1172-39 and MAE 836.57. Even the worst Random Forest Regression model was better than the best Linear Regression model.

What lead size: I diminimum number of observations per leaf.

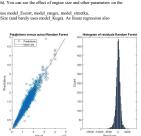

Method: Bag. Random forest longing.

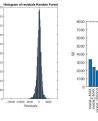

Number of Cleaning cycles: 100. Number of decision tree regressors to use in the forest.

Using K-fold cross-validation, 100 frees and taking the average of the results we get almost as good a result as just using 100 trees, but not quite as good as just using 100 trees
